# Craterium corniculatum sp. nov. from northwestern China

Bo Zhang¹ & Yu Li¹\*

<sup>1</sup>Engineering Research Center of Chinese Ministry of Education for Edible and Medicinal Fungi, Jilin Agricultural University, 2888 Xincheng Street, Changchun City, P. R. China

ABSTRACT — Craterium corniculatum is a new species collected in Gansu Province, China, characterized by horned sporophores and warted spores. We provide a morphological description, illustrations, and a key to the 17 Craterium species. The specimens were deposited in the Herbarium of Mycological Institute of Jilin Agricultural University (HMJAU), Changchun, China.

KEY WORDS — taxonomy, SEM, slime molds, Myxogastrea, Physaraceae

#### Introduction

Myxomycetes are common inhabitants of decaying plant materials in nature, such as decaying logs, stumps, and dead leaves (Stephenson & Stempen 1994). Trentepohl established the genus *Craterium* in 1797 for myxomycetes with stalked sporophores, a persistent basal cup, and subglobose or turbinate obovate sporocarps that show a distinct or indistinct lid during dehiscence (Martin & Alexopoulos 1969). In 2012 we found a new species on the bark of a dead log on Jilian Mountain, Gansu Province, China, that differs morphologically from all other *Craterium* species.

### Materials & methods

The fruiting bodies and microscopic structures were examined by light and scanning electron microscopes (Martin & Alexopoulos 1969, Zhang & Li 2013). Permanent slides were mounted in Hoyer's reagent (Martin & Alexopoulos 1969). We prepared them according to Robbrecht (1974) by spreading capillitia in a drop of 94% alcohol, determining colour after one minute, and then mounting in Hoyer's reagent. Colour terms are given according to Flora of British Fungi (Royal Botanic Garden Edinburgh 1969).

We observed more than ten sporocarps under a stereomicroscope (20×) and more than 20 spores under an optical microscope (100×). The sporophores, capillitia, and

<sup>\*</sup> Correspondence to: yuli966@126.com

spores were measured by using a Nikon DM1000 microscope and photographed with a Canon G15 camera. For ultrastructural observation, the sporophores were attached to the holder, coated with gold using a Hitachi E-1010 sputter, and examined with a Hitachi S-4800 scanning electron microscope at 10 kV at Changchun Institute of Applied Chemistry, Chinese Academy of Sciences. The specimens were deposited in the Herbarium of Mycological Institute, Jilin Agricultural University (HMJAU).

## **Taxonomy**

# Craterium corniculatum B. Zhang & Yu Li, sp. nov.

Plate 1

MYCOBANK MB 806043

Differs from Craterium aureomagnum and C. aureum by its horned sporophores and warted spores.

Type: China, Gansu Province, Jilan Mountain, on bark of a dead log, 6 August 2012, Zhang Bo 20122203, (Holotype, HMJAU10550).

ETYMOLOGY: corniculatus (Latin), referring to the 'horned' sporophores.

Sporophores gregarious, in small groups, shortly stalked or nearly sessile, 0.25–0.75 mm tall. Sporotheca subglobose or pyriform to irregular, 0.2–0.5 mm in diam. Hypothallum conspicuous, membranous, pale yellow, veined with ribs radiating from the sporocarp base. Stalk either lacking, or very short and consisting of updrawn hypothallus, strongly ribbed, yellowish brown, pale brown in transmitted light. Lid paler than cup, usually with a paler calcareous deposit, yellowish pale by transmitted light, with pale dehiscence lines and circumscissile area. Peridium thick, single, cartilaginous, containing small lime. Capillitum rather dense, lime nodes rounded or angular, large, pale yellowish brown by transmitted light,  $40 \times 70$ –80(–100) µm. Spores free, fuscous black in mass, dark brown by transmitted light, subglobose, 8–14 µm diam., densely warted.

Additional specimen examined: CHINA, Gansu Province, Jilan Mountain, on bark of a dead log, 26 August 2010, Zhang Bo 20101201 (HMJAU10551).

Comments: Of the 16 species reported for *Craterium* Trentep. (Kirk et al. 2008, Lado 2005–13), seven have been found in China: *C. aureum* (Schumach.) Rostaf., *C. concinnum* Rex, *C. leucocephalum* (Pers. ex J.F. Gmel.) Ditmar, *C. microcarpum* H.Z. Li et al., *C. minutum* (Leers) Fr., *C. obovatum* Peck, and *C. rubronodum* G. Lister (Li & Li 1989, Li et al. 1993). Among the 16 accepted species, only *C. aureomagnum* Hooff & Nann.-Bremek. and *C. aureum* are similar to *C. corniculatum* in having yellow sporocarps, but *C. aureomagnum* has larger sporocarps (0.7–1.5 mm tall), double peridia, and darker and prominently warted spores that are 10–12 µm in diam. (Hooff & Nannenga-Bremekamp 1996), while *C. aureum* has stalked, turbinate, or obovoid sporocarps that are 0.7–1.0 mm tall and lemon-yellow to almost white (Rostafinski 1974).

| 6. Sporocarps short (0.5–0.8 mm high); spores 9–10 $\mu m$ in diam                       | ncinnum   |
| 6. Sporocarps taller ( $\leq\!1.5$ mm high); spores 8–10 $\mu m$ in diam. $$             | minutum   |

| 7. Spores 10–12 μm in diam. with 1μm tall spines  |  |
|---|--|
| 7. Spores 13–15 $\mu m$ in diam. with groups of confluent spines                                    |  |
| 8. Sporophores obconic; becoming cup-shaped after dehiscence  |  |
| 8. Sporophores obovoid, turbinate, corniculate; dehiscence irregular                                |  |
| 9. Sporocarps usually stalked; spores 7–10 μm in diam   |  |
| 9. Sporocarps sessile or short-stalked; spores 9–10 $\mu m$ in diam C. aureonucleatum               |  |
| 10. Sporocarps yellow 11  |  |
| 10. Sporocarps bright pink, purplish pink, red brown  |  |
| 11. Sporocarps stalked  |  |
| 11. Sporocarps sessile or very short-stalked  |  |
| 12. Sporocarps subcylindric; spores 10–12 μm in diam  |  |
| 12. Sporocarps corniculate; spores 8–14 μm in diam  |  |
| 13. Sporocarps bright pink, purplish pink   |  |
| 13. Sporocarps red brown, purplish brown, dark brown to black                                       |  |
| 14. Spores warted, <13 $\mu m$ in diam  |  |
| 14. Spores coarsely warted, subreticulate or reticulate, >13 $\mu m$ in diam                        |  |
| 15. Spores with dark prominent warts  |  |
| 15. Spores subreticulate or reticulate  |  |
| 16. Spores marked with an incomplete net of broad spines fusing into short ridges, 14–17 µm in diam |  |
| 16. Spores loosely reticulate by ridges about 1 μm high, 13–16 μm in                                |  |
| diam  |  |

### Acknowledgments

We express our deep appreciation to Prof. Guozhong Lü (Dalian Nationalities University, P.R. China) and Prof. A.J.S. Whalley for their valuable suggestions in peer-reviewing this manuscript. We thank Tianhao Li, Jilin Agricultural University for correcting the manuscript. The study was supported by the fund from the Ministry of Agriculture of China.
